Sample Question: Calculus and Differential Equations

Question

A particle moves along a straight line such that its velocity $v(t)$ at time t seconds is given by:

[

$$v(t) = 3t^2 - 4t + 2$$

]

where $v(t)$ is in meters per second. Find:

- The displacement of the particle from $t = 0$ to $t = 4$ seconds.
- The total distance traveled by the particle in this interval.

Step-by-Step Solution with Explanation

Part (a): Calculating Displacement

Displacement over an interval can be found by integrating the velocity function:

$$\text{Displacement} = \int_a^b v(t) \, dt$$

For t from 0 to 4 seconds:

$$\text{Displacement} = \int_0^4 (3t^2 - 4t + 2) \, dt$$

Step 1: Find the indefinite integral

$$\int (3t^2 - 4t + 2) \, dt = t^3 - 2t^2 + 2t + C$$

Step 2: Evaluate the definite integral

$$\left[t^3 - 2t^2 + 2t \right]_0^4$$

Plug in $(t = 4)$:

$$4^3 - 2 \times 4^2 + 2 \times 4 = 64 - 2 \times 16 + 8 = 64 - 32 + 8 = 40$$

Plug in $(t = 0)$:

$$0 - 0 + 0 = 0$$

Result:

$$\text{Displacement} = 40 \text{ meters}$$

Part (b): Calculating Total Distance Traveled

Total distance considers the direction changes; it is the integral of the absolute value of the velocity over the interval. Because velocity may change sign, we need to identify when $(v(t) = 0)$ within the interval, to split the integral accordingly.

Step 1: Find when $(v(t) = 0)$

$$3t^2 - 4t + 2 = 0$$

Solve the quadratic:

$$t = \frac{4 \pm \sqrt{(-4)^2 - 4 \times 3 \times 2}}{2 \times 3} = \frac{4 \pm \sqrt{16 - 24}}{6}$$

]

[

$$t = \frac{4 \pm \sqrt{-8}}{6}$$

]

Since the discriminant is negative, the quadratic has no real roots, meaning $v(t)$ does not change sign in the interval $[0, 4]$.

Step 2: Determine the sign of $v(t)$ in $[0, 4]$

Pick a test point, say $t = 1$:

[

$$v(1) = 3(1)^2 - 4(1) + 2 = 3 - 4 + 2 = 1 > 0$$

]

Since the velocity is positive at $t = 1$, and the quadratic has no real roots, the velocity remains positive throughout $[0, 4]$.

Step 3: Compute total distance

Because the velocity is positive over the entire interval:

[

$$\text{Total Distance} = \int_0^4 v(t) \, dt = 40 \text{ meters}$$

]

Note: If $v(t)$ had changed sign, we would need to split the integral at the roots and take absolute values accordingly.

Summary of the Solution

| Part | Calculation | Result |

|-----|-----|-----|

| (a) Displacement | $\int_0^4 (3t^2 - 4t + 2) dt$ | 40 meters |

| (b) Total Distance | Since $v(t) > 0$ in $[0, 4]$ | 40 meters |

Additional Tips for Students

- **Practice Integration Techniques:** Master basic integrals as they form the foundation for solving such problems.
- **Check Sign Changes:** Always verify whether the velocity function changes sign within the interval to determine whether you need to consider absolute values.
- **Understand the Concept of Displacement vs. Distance:** Displacement is the net change in position, while total distance accounts for actual path traveled, regardless of direction.
- **Use Graphical Methods:** Sketching the velocity graph can help visualize sign changes and the particle's motion.
- **Review Quadratic Roots:** Solving quadratic equations accurately is crucial for identifying points where velocity changes sign.

Typical Topics Covered in Diploma Mathematics 1

Diploma Mathematics 1 usually encompasses fundamental topics such as:

- Algebra
- Trigonometry
- Coordinate Geometry
- Calculus (Basics)
- Sequences and Series

For the purpose of this article, we will focus on a classic problem from the coordinate geometry section, which often appears in exams.

Sample Question: Solved Problem from Coordinate Geometry

Question:

Find the equation of the line passing through the points $(A(2, 3))$ and $(4, 7)$, and determine whether the line is parallel or perpendicular to the line passing through points $(B(1, 2))$ and $(3, 5)$.

Step-by-Step Solution and Explanation

Step 1: Find the slope of the first line passing through points $(A(2, 3))$ and $(C(4, 7))$

The slope (m_1) of a line passing through two points $((x_1, y_1))$ and $((x_2, y_2))$ is given by:

[

$$m_1 = \frac{y_2 - y_1}{x_2 - x_1}$$

]

Substituting the values:

[

$$m_1 = \frac{7 - 3}{4 - 2} = \frac{4}{2} = 2$$

]

This indicates that the slope of the first line is 2.

Step 2: Find the slope of the second line passing through points $(B(1, 2))$ and $(D(3, 5))$

Similarly, the slope (m_2) :

[

$$m_2 = \frac{5 - 2}{3 - 1} = \frac{3}{2}$$

]

So, the slope of the second line is $(\frac{3}{2})$.

Step 3: Determine the relationship between the two lines

- Parallel lines have equal slopes: $(m_1 = m_2)$
- Perpendicular lines have slopes that are negative reciprocals: $(m_1 \times m_2 = -1)$

Calculating the product:

$\backslash$

$$m_1 \times m_2 = 2 \times \frac{3}{2} = 3$$

$\backslash$

Since the product is 3, which is neither 1 nor -1, the lines are neither parallel nor perpendicular.

Step 4: Find the equation of the first line passing through point $(A(2, 3))$ with slope (2)

Using the point-slope form:

$\backslash$

$$y - y_1 = m (x - x_1)$$

$\backslash$

Substituting:

$\backslash$

$$y - 3 = 2 (x - 2)$$

$\backslash$

Simplify:

$\backslash$

$$y - 3 = 2x - 4$$

$\backslash$

$\backslash$

$$y = 2x - 4 + 3$$

\]

\[

$$\boxed{y = 2x - 1}$$

\]

This is the equation of the line passing through points (A) and (C) .

Summarizing the Key Results

- The slope of the first line: 2
- The slope of the second line: $\frac{3}{2}$
- The lines are neither parallel nor perpendicular
- Equation of the first line: $y = 2x - 1$

Additional Insights and Tips for Students
